Question1:

Falling Glass

(a) Describe the optimal substructure/recurrence that would lead to a recursive solution

m is number of glass sheets n is the number of floors.

When drop the glass sheet from a floor i, there is two cases:

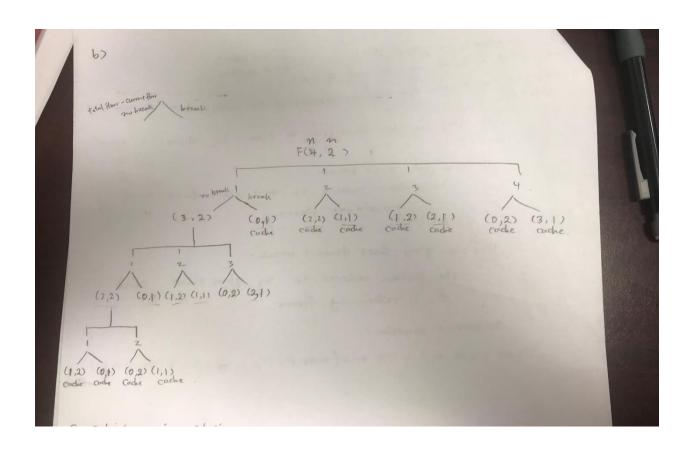

Case1: The glass sheet break:

The problem reduces to m -1 glass sheet and i -1 remaining floors.

Case2: The glass sheet doesn't break:

Then problem reduces to m glass sheet and n-i remaining floors.

(b) Draw recurrence tree for given (floors = 4, sheets = 2)

(c) Code your recursive solution under GlassFallingRecur(int n numFloors, int m numGlass)
(d) How many distinct subproblems do you end up with given 4 floors and 2 sheets? Answer: 4*2 = 8 distinct subproblems
(e) How many distinct subproblems for n floors and m sheets?
Answer: n*m distinct subproblems (f) Describe how you would memoize GlassFallingRecur
Answer: step 1 create a cache to store temporary results.
Step 2 Before performing a calculation, check whether the calculation has already been done, if its already done, use the store result.
Step 3 if the value is first time calculate, store the results for later use.
(g) Code a bottom-up solution GlassFallingBottomUp(int n numFloors, int m numGlass)
github
GlassFalling Output:

```

```

Q2. Rod Cutting

(a) Draw the recursion tree for a rod of length 5

(b) On page 370: answer 15.1-2 by coming up with a counterexample, meaning come up with a situation / some input that shows we can only try all the options via dynamic programming instead of using a greedy choice.

Answer: let p1 = 1, p2 = 5, p3 = 8, p4=9 and n =4 Density: 1/1 = 1, 5/2 = 2.5, 8/3 = 2.667, 9/4=2.25.

Max density is 8/3 so the greedy first cut off a piece of length of 3, the remaining will be 1 + 1 = 9 total profit. But if cut the rob with length of 2 will give 5 + 5 = 10 which is higher than 9.

(c) Code the memoized recursive version in RodCutting.java under rodCuttingRecur github

(d) Code the bottom-up solution in RodCutting.java under rodCuttingBottomUp

Github
